Federal Energy R&D: Carbon Storage and Utilization

This briefing is part of a series on the U.S. energy budget. See: itif.org/energy-budget.

The Carbon Storage and Utilization programs are focused on the development of technologies for the safe use and permanent storage of captured carbon dioxide (CO₂). The storage program focuses on developing the technologies and infrastructure necessary to store captured CO₂ safely in deep saline formations or oil and natural gas reservoirs. The carbon use and reuse program focuses on recycling captured CO₂ into valuable products, such as chemicals, fuels, and building materials.

Figure 1: The FY 2021 budget request would cut carbon storage and utilization R&D by 55 percent.

What's at Risk
Preliminary research suggests the United States has enough subsurface capacity to permanently sequester 1.71 trillion metric tons of CO₂, which is the equivalent of 950 years of carbon emissions from power plants at 2016 levels. However, additional cost reductions, validation, safety testing, and mitigation research are necessary to realize this capacity. While the size of many subsurface storage reservoirs has been initially characterized, detailed site-specific work is required to confirm their potential. Research and development (R&D) is also needed for tools to map and simulate below-ground fractures and faults with a high degree of resolution and fidelity, devise wellbore materials that can better resist corrosion by CO₂-saturated brine, and improve the ability to monitor and mitigate the risk of induced seismicity from the injection of CO₂.
underground. And large-scale, long-term demonstration projects are necessary to ensure captured CO₂ is safely and permanently stored.

In April 2017, the Illinois Industrial Carbon Capture and Storage project—funded jointly by the Department of Energy (DOE) and private investors—began capturing CO₂ from an ethanol production facility and storing it underground in a saline reservoir at a rate of one million metric tons of CO₂ per year. This large, first-of-a-kind demonstration project is testing and validating technologies while concurrently endeavoring to reduce future costs.⁴ In 2018, DOE selected three additional cost-shared R&D projects to identify sites that could store more than 50 million metric tons of CO₂ as part of its Carbon Storage Assurance Facility Enterprise (CarbonSAFE) initiative.⁵ The proposed budget would substantially cut funding for these efforts.

Carbon utilization—turning CO₂ from a waste product into a product of value—is key to expanding the market for CO₂ and incenting greater carbon capture. But many potential uses for captured carbon, such as carbon nanotubes and synthetic hydrocarbon fuels, are far from commercialized, and require further R&D in order to bring costs down. In 2019, the National Academies developed a broad innovation agenda for chemical and biological conversion of CO₂ into fuels and chemicals, but funding at DOE has been insufficient to address the full suite of research, development, and demonstration needs identified by the National Academies.⁶

**Carbon Storage and Utilization R&D Activities**

Funding for carbon storage and utilization R&D is spread across four activities:

- **Storage Infrastructure R&D** focuses on geologic resource characterization and small- and large-scale field projects to demonstrate permanent geologic storage; validation of injection, simulation/risk assessment, and monitoring strategies; and assessment of the probability, and subsequent mitigation, of potential seismic events. Program activities include the CarbonSAFE initiative, which funds industry cost-shared R&D projects to characterize and develop commercial-scale (more than 50 million metric tons of CO₂) storage complexes by 2025; the Brine Extraction Storage Test (BEST), which advances strategies for managing subsurface pressure and fluid flow; and the seven Regional Carbon Sequestration Partnerships (RCSPs), which are currently testing large-scale CO₂ injection and storage technologies.⁷

- **Advanced Storage R&D** is focused on validating storage monitoring, simulation, risk assessment, and advanced wellbore technologies to detect and mitigate wellbore issues. R&D activities include developing CO₂-resistant construction materials and well-integrity technologies, plus technologies to detect and mitigate potential CO₂ leakage pathways.

- **Sub-disciplinary Storage R&D** focuses on assessment and validation of subsurface models; support for the National Risk Assessment Partnership (NRAP), with a focus on storage risk tools; and development of the Energy Data
Exchange (EDX) system, which supports data management and technology transfer. The budget request proposes merging the subprogram with Advanced Storage R&D.8

- **Carbon Use & Reuse R&D** explores the beneficial reuse of CO₂, including conversion into higher-value products such as chemicals, plastics, and building materials, and accelerated curing for cement. The primary objective is to lower the near-term cost of carbon capture, utilization, and sequestration (CCUS) through the creation of value-added products via the conversion of CO₂.

### Key Elements of the FY 2021 Budget Proposal

- **A 91 percent reduction in Storage Infrastructure R&D**, and no funding for activities other than “infrastructure network studies and cost and performance analyses.” It is unclear whether the CarbonSAFE Initiative, BEST, or the RCSPs would continue to be supported. Long-term, ongoing evaluation and monitoring of storage test sites is necessary to provide confidence that captured CO₂ is safely and permanently stored.

- **A 14 percent increase in Advanced Storage R&D** (which would be merged with Sub-disciplinary Storage R&D), with the increased funding focused on efforts to advance machine learning/artificial intelligence (ML/Al) tools to support subsurface storage decision-making.

- **A 29 percent reduction in Carbon Use & Reuse R&D**, with reduced funding supporting laboratory- and bench-scale activities to convert CO₂ into chemicals, building materials, and solid carbon.

### ENDNOTES

**ABOUT THE AUTHORS**

Colin Cunliff is a senior policy analyst for clean energy innovation with the Information Technology and Innovation Foundation. He previously worked at the U.S. Department of Energy (DOE) Office of Energy Policy and Systems Analysis (EPSA), with a portfolio focused on energy sector resilience and emissions mitigation. He holds a Ph.D. in physics from the University of California, Davis.

Batt Odgerel is a policy fellow for clean energy innovation at the Information Technology and Innovation Foundation. He previously worked for the Energy Policy Research Foundation (EPRINC) and Smart Electric Power Alliance (SEPA). Batt holds a master’s degree in energy policy from Johns Hopkins University’s School of Advanced International Studies, Washington, D.C.

**ABOUT ITIF**

The Information Technology and Innovation Foundation (ITIF) is a nonprofit, nonpartisan research and educational institute focusing on the intersection of technological innovation and public policy. Recognized as the world’s leading science and technology think tank, ITIF’s mission is to formulate and promote policy solutions that accelerate innovation and boost productivity to spur growth, opportunity, and progress.
